

$R_k = \alpha 1[d_k=y] - \lambda (p_k - 1[d_k=y])^2 - \kappa C[y, d_k] - c \cdot \text{cost}(\text{tests after } s)$; $K = 3$. In a forced continuation, a **DEFER** is executed as **COMMIT** of its differential's top; tests remain allowed. V_τ : reward of a calibrated decision that succeeds with probability τ (1.2 on OTHER cases). S : normalised multi-class Brier score of the handed-over differential q (strictly proper). $\mu = 0.1$: handoff cost. ν : coverage multiplier (Fig. S1).
